

1. The `==` operator will result in type conversion when appropriate while the `===` meaning `0 == false` will return true while `0 === false` will return false
2. Closure means that, for each call to a function, the function will create new local bindings.
3. Higher order functions take other functions as arguments or return them
4. A query selector will select the first element from a document that corresponds to the selector or selectors: `element = document.querySelector(selector(s))`
